

## EXHIBIT 043

**U.S. Patent No. 8,086,800 (Radulescu and Goossens)**

“Integrated circuit and method for buffering to optimize burst length in networks on chips”

'800 Patent Claim	OnePlus Product Including Snapdragon System on Chip <sup>1</sup>
10. A method for buffering data in an integrated circuit having a plurality of processing modules being connected with an interconnect through interface units, wherein a first processing module communicates to a second processing module using transactions, the method comprising the acts of:	<p>Without conceding that the preamble of claim 10 of the '800 Patent is limiting, the OnePlus 10T (hereinafter, the “OnePlus product”) performs a method for buffering data in an integrated circuit having a plurality of processing modules being connected with an interconnect through interface units, wherein a first processing module communicates to a second processing module using transactions), either literally or under the doctrine of equivalents.</p> <p>The OnePlus product includes an integrated circuit. For example, the OnePlus product includes the Snapdragon 8+ Gen 1 Mobile Platform system on chip (hereinafter, the “Snapdragon SoC”).</p>  <p><b>OnePlus 10T</b> Powered by Snapdragon 8+ Gen 1 Mobile Platform OnePlus 10T 5G is the speed-leading flagship delivering ultimate performance. Driven relentlessly by the fastest charging in OnePlus history and the powerful Snapdragon 8+ Gen 1 mobile platform, this is a phone built to evolve beyond speed. It has Qualcomm FastConnect 6900 for premium Wi-Fi connectivity and a Kryo CPU for unbeatable performance.</p> <p><a href="https://www.qualcomm.com/snapdragon/device-finder/smartphones/oneplus-10t">https://www.qualcomm.com/snapdragon/device-finder/smartphones/oneplus-10t</a></p>

<sup>1</sup> The OnePlus product is charted as a representative product made used, sold, offered for sale, and/or imported by OnePlus. The citations to evidence contained herein are illustrative and should not be understood to be limiting. The right is expressly reserved to rely upon additional or different evidence, or to rely on additional citations to the evidence cited already cited herein.

"Integrated circuit and method for buffering to optimize burst length in networks on chips"

'800 Patent Claim	OnePlus Product Including Snapdragon System on Chip <sup>1</sup>
	<p>NoC, "[m]ost transactions require the following two-step transfers," including "[a] master send[ing] request packets" and "the slave return[ing] response packets":</p> <p><b>11.3.1.1 Transaction Layer</b></p> <p>The transaction layer is compatible with bus-based transaction protocols used for on-chip communications. It is implemented in NIUs, which are at the boundary of the NoC, and translates between third-party and NTTP protocols. Most transactions require the following two-step transfers:</p> <ul style="list-style-type: none"> <li>• A master sends request packets.</li> <li>• Then, the slave returns response packets.</li> </ul> <p>As shown in Figure 11.1, requests from an initiator are sent through the master NIU's transmit port, Tx, to the NoC request network, where they are routed to the corresponding slave NIU. Slave NIUs, upon reception of request packets on their receive ports, Rx, translate requests so that they comply with the protocol used by the target third-party IP node. When the target node responds, returning responses are again converted by the slave NIU into appropriate response packets, then delivered through the slave NIU's Tx port to the response network. The network then routes the response packets to the requesting master NIU, which forwards them to the initiator. At the transaction level, NIUs enable multiple protocols to coexist within the same NoC. From the point of view of the NTTP modules, different third-party protocols are just packets moving back and forth across the network.</p>

	<p><b>11.3.2 Network Interface Units</b></p> <p>The Arteris Danube IP library includes NIUs for different third party protocols. Currently, three different protocols are supported: AHB (APB), OCP, and AXI. For each protocol, two different NIU units can be instantiated:</p> <ul style="list-style-type: none"> <li>• <b>Initiator NIU</b>—third party protocol-to-NTTP, used to connect a master node to the NoC</li> <li>• <b>Target NIUs</b>—NTTP-to-third party protocol, used to connect a slave node to the NoC</li> </ul> <p>Networks-On-Chips Theory and Practice, <a href="https://vdoc.pub/download/networks-on-chips-theory-and-practice-embedded-multi-core-systems-6f26qivv11f0">https://vdoc.pub/download/networks-on-chips-theory-and-practice-embedded-multi-core-systems-6f26qivv11f0</a>, at 316-317.</p> <p>As a further example, "Initiator NIU units...enable connection between an AMBA-AHB master IP and the NoC [and] translate[] AHB transactions AHB transactions into an equivalent NTTP packet sequence, and transports requests and responses to and from a target NIU, that is, slave IP" and has a "FIFO memory [...] inserted in the datapath for AHB write access":</p>

U.S. Patent No. 8,086,800 (Radulescu and Goossens)

"Integrated circuit and method for buffering to optimize burst length in networks on chips"

'800 Patent Claim	OnePlus Product Including Snapdragon System on Chip <sup>1</sup>
	<p><b>11.3.2.1 <i>Initiator NIU Units</i></b></p> <p>Initiator NIU units (the architecture of the AHB initiator is given in Figure 11.4) enable connection between an AMBA-AHB master IP and the NoC. It translates AHB transactions into an equivalent NTTP packet sequence, and transports requests and responses to and from a target NIU, that is, slave IP (slave can be any of the supported protocols). The AHB-to-NTTP unit instantiates a Translation Table for address decoding. This table receives 32-bit AHB addresses from the NIU and returns the packet header and necker information that is needed to access the NTTP address space: Slave address, Slave offset, Start offset, and the coherency size (see <a href="#">Figure 11.2</a>). Whenever the AHB address does not fit the predefined decoding range, the table asserts an error signal that sets the error bit of the corresponding NTTP request packet, for further error handling by the NoC. The translation table is fully user-defined at design time: it must first be completed with its own hardware parameters, then passed to the NIU.</p> <p>A FIFO memory is inserted in the datapath for AHB write accesses. The FIFO memory absorbs data at the AHB initiator rate, so that NTTP packets can</p>

'800 Patent Claim	OnePlus Product Including Snapdragon System on Chip <sup>1</sup>
	<p>burst at NoC rate as soon as a minimum amount of data has been received. The width of the FIFO and the AHB data bus is identical, and the FIFO depth is defined by the hardware parameter. This parameter indicates the amount of data required to generate a Store packet: each time the FIFO is full, a Request packet is sent on the Tx port. Of course, if the AHB access ends before the FIFO is full, the NTTP request packet is sent. Because AHB can only tolerate a single outstanding transaction, the AHB bus is frozen until the NTTP transaction has been completed. That is</p> <ul style="list-style-type: none"> <li>• During a read request, until the requested data arrives from the Rx port</li> <li>• During a nonbufferable write request, in which case only the last access is frozen and the acknowledge occurs when the last NTTP response packet has been received</li> <li>• When an internal FIFO is full</li> </ul>

**U.S. Patent No. 8,086,800 (Radulescu and Goossens)**

“Integrated circuit and method for buffering to optimize burst length in networks on chips”

'800 Patent Claim	OnePlus Product Including Snapdragon System on Chip <sup>1</sup>
	<p><b>11.3.2 Network Interface Units</b></p> <p>The Arteris Danube IP library includes NIUs for different third party protocols. Currently, three different protocols are supported: AHB (APB), OCP, and AXI. For each protocol, two different NIU units can be instantiated:</p> <ul style="list-style-type: none"> <li>• <b>Initiator NIU</b>—third party protocol-to-NTTP, used to connect a master node to the NoC</li> <li>• <b>Target NIUs</b>—NTTP-to-third party protocol, used to connect a slave node to the NoC</li> </ul> <p>Networks-On-Chips Theory and Practice, <a href="https://vdoc.pub/download/networks-on-chips-theory-and-practice-embedded-multi-core-systems-6f26qivv11f0">https://vdoc.pub/download/networks-on-chips-theory-and-practice-embedded-multi-core-systems-6f26qivv11f0</a>, at 316-317.</p> <p>As further example, “Target NIU units enable connection of a slave IP to the NoC by translating NTTP packet sequences into equivalent packet transactions, and transporting requests and responses to and from targets” and have a FIFO memory in the datapath:</p>

**U.S. Patent No. 8,086,800 (Radulescu and Goossens)**

“Integrated circuit and method for buffering to optimize burst length in networks on chips”

'800 Patent Claim	OnePlus Product Including Snapdragon System on Chip <sup>1</sup>
	<p><b>11.3.2.2 Target NIU Units</b></p> <p>Target NIU units enable connection of a slave IP to the NoC by translating NTTP packet sequences into equivalent packet transactions, and transporting requests and responses to and from targets (the architecture of the AHB Target NIU is given in Figure 11.5). For the AHB target NIU, the AHB address space is mapped from the NTTP address space using the slave offset, the start/stop offset, and the slave address fields, when applicable (from the header of the request packet, <a href="#">Figure 11.2</a>). The AHB address bus is always 32 bits wide, but the actual address space size may be downsized by setting a hardware parameter. Unused AHB address bits are then driven to zero. The NTTP request packet is then translated into one or more corresponding AHB accesses, depending on the transaction type (word aligned or nonaligned access). For example, if the request is an atomic Store, or a Load that can fit an AHB burst of specified length, then such a burst is generated. Otherwise, an AHB burst with unspecified length is generated.</p>

'800 Patent Claim	OnePlus Product Including Snapdragon System on Chip <sup>1</sup>
	<p><b>11.3.2.1 Initiator NIU Units</b></p> <p>Initiator NIU units (the architecture of the AHB initiator is given in Figure 11.4) enable connection between an AMBA-AHB master IP and the NoC. It translates AHB transactions into an equivalent NTTP packet sequence, and transports requests and responses to and from a target NIU, that is, slave IP (slave can be any of the supported protocols). The AHB-to-NTTP unit instantiates a Translation Table for address decoding. This table receives 32-bit AHB addresses from the NIU and returns the packet header and necker information that is needed to access the NTTP address space: Slave address, Slave offset, Start offset, and the coherency size (see <a href="#">Figure 11.2</a>). Whenever the AHB address does not fit the predefined decoding range, the table asserts an error signal that sets the error bit of the corresponding NTTP request packet, for further error handling by the NoC. The translation table is fully user-defined at design time: it must first be completed with its own hardware parameters, then passed to the NIU.</p> <p>A FIFO memory is inserted in the datapath for AHB write accesses. The FIFO memory absorbs data at the AHB initiator rate, so that NTTP packets can</p>

	<p>on their receive ports, Rx, translate requests so that they comply with the protocol used by the target third-party IP node. When the target node responds, returning responses are again converted by the slave NIU into appropriate response packets, then delivered through the slave NIU's Tx port to the response network. The network then routes the response packets to the requesting master NIU, which forwards them to the initiator. At the transaction level, NIUs enable multiple protocols to coexist within the same NoC. From the point of view of the NTTP modules, different third-party protocols are just packets moving back and forth across the network.</p>

'800 Patent Claim	OnePlus Product Including Snapdragon System on Chip <sup>1</sup>
	<p><b>11.3.2.2 Target NIU Units</b></p> <p>Target NIU units enable connection of a slave IP to the NoC by translating NTTP packet sequences into equivalent packet transactions, and transporting requests and responses to and from targets (the architecture of the AHB Target NIU is given in Figure 11.5). For the AHB target NIU, the AHB address space is mapped from the NTTP address space using the slave offset, the start/stop offset, and the slave address fields, when applicable (from the header of the request packet, <a href="#">Figure 11.2</a>). The AHB address bus is always 32 bits wide, but the actual address space size may be downsized by setting a hardware parameter. Unused AHB address bits are then driven to zero. The NTTP request packet is then translated into one or more corresponding AHB accesses, depending on the transaction type (word aligned or nonaligned access). For example, if the request is an atomic Store, or a Load that can fit an AHB burst of specified length, then such a burst is generated. Otherwise, an AHB burst with unspecified length is generated.</p>

	<p>defined by the hardware parameter" which "indicates the amount of data required to generate a Store packet: each time the FIFO is full, a Request packet is sent on the Tx port":</p> <p><b>11.3.2.1 Initiator NIU Units</b></p> <p>Initiator NIU units (the architecture of the AHB initiator is given in Figure 11.4) enable connection between an AMBA-AHB master IP and the NoC. It translates AHB transactions into an equivalent NTTP packet sequence, and transports requests and responses to and from a target NIU, that is, slave IP (slave can be any of the supported protocols). The AHB-to-NTTP unit instantiates a Translation Table for address decoding. This table receives 32-bit AHB addresses from the NIU and returns the packet header and necker information that is needed to access the NTTP address space: Slave address, Slave offset, Start offset, and the coherency size (see <a href="#">Figure 11.2</a>). Whenever the AHB address does not fit the predefined decoding range, the table asserts an error signal that sets the error bit of the corresponding NTTP request packet, for further error handling by the NoC. The translation table is fully user-defined at design time: it must first be completed with its own hardware parameters, then passed to the NIU.</p> <p>A FIFO memory is inserted in the datapath for AHB write accesses. The FIFO memory absorbs data at the AHB initiator rate, so that NTTP packets can</p>

'800 Patent Claim	OnePlus Product Including Snapdragon System on Chip <sup>1</sup>
	<p><b>11.3.2.2 Target NIU Units</b></p> <p>Target NIU units enable connection of a slave IP to the NoC by translating NTTP packet sequences into equivalent packet transactions, and transporting requests and responses to and from targets (the architecture of the AHB Target NIU is given in Figure 11.5). For the AHB target NIU, the AHB address space is mapped from the NTTP address space using the slave offset, the start/stop offset, and the slave address fields, when applicable (from the header of the request packet, <a href="#">Figure 11.2</a>). The AHB address bus is always 32 bits wide, but the actual address space size may be downsized by setting a hardware parameter. Unused AHB address bits are then driven to zero. The NTTP request packet is then translated into one or more corresponding AHB accesses, depending on the transaction type (word aligned or nonaligned access). For example, if the request is an atomic Store, or a Load that can fit an AHB burst of specified length, then such a burst is generated. Otherwise, an AHB burst with unspecified length is generated.</p>

It translates AHB transactions into an equivalent NTTP packet sequence, and transports requests and responses to and from a target NIU, that is, slave IP (slave can be any of the supported protocols). The AHB-to-NTTP unit instantiates a Translation Table for address decoding. This table receives 32-bit AHB addresses from the NIU and returns the packet header and necker information that is needed to access the NTTP address space: Slave address, Slave offset, Start offset, and the coherency size (see <a href="#">Figure 11.2</a>). Whenever the AHB address does not fit the predefined decoding range, the table asserts an error signal that sets the error bit of the corresponding NTTP request packet, for further error handling by the NoC. The translation table is fully user-defined at design time: it must first be completed with its own hardware parameters, then passed to the NIU.</p> <p>A FIFO memory is inserted in the datapath for AHB write accesses. The FIFO memory absorbs data at the AHB initiator rate, so that NTTP packets can</p>

	<p><b>11.3.1.1 <i>Transaction Layer</i></b></p> <p>The transaction layer is compatible with bus-based transaction protocols used for on-chip communications. It is implemented in NIUs, which are at the boundary of the NoC, and translates between third-party and NTTP protocols. Most transactions require the following two-step transfers:</p> <ul style="list-style-type: none"> <li>• A master sends request packets.</li> <li>• Then, the slave returns response packets.</li> </ul> <p>As shown in Figure 11.1, requests from an initiator are sent through the master NIU's transmit port, Tx, to the NoC request network, where they are routed to the corresponding slave NIU. Slave NIUs, upon reception of request packets on their receive ports, Rx, translate requests so that they comply with the protocol used by the target third-party IP node. When the target node responds, returning responses are again converted by the slave NIU into appropriate response packets, then delivered through the slave NIU's Tx port to the response network. The network then routes the response packets to the requesting master NIU, which forwards them to the initiator. At the transaction level, NIUs enable multiple protocols to coexist within the same NoC. From the point of view of the NTTP modules, different third-party protocols are just packets moving back and forth across the network.</p>

As further example, "Target NIU units enable connection of a slave IP to the NoC by translating NTTP packet sequences into equivalent packet transactions, and transporting requests and responses to and from targets" and includes blocks such as "Data FIFO" and "Packet Assembly":

U.S. Patent No. 8,086,800 (Radulescu and Goossens)

"Integrated circuit and method for buffering to optimize burst length in networks on chips"

'800 Patent Claim	OnePlus Product Including Snapdragon System on Chip <sup>1</sup>
	<p><b>11.3.2.2 Target NIU Units</b></p> <p>Target NIU units enable connection of a slave IP to the NoC by translating NTTP packet sequences into equivalent packet transactions, and transporting requests and responses to and from targets (the architecture of the AHB Target NIU is given in Figure 11.5). For the AHB target NIU, the AHB address space is mapped from the NTTP address space using the slave offset, the start/stop offset, and the slave address fields, when applicable (from the header of the request packet, <a href="#">Figure 11.2</a>). The AHB address bus is always 32 bits wide, but the actual address space size may be downsized by setting a hardware parameter. Unused AHB address bits are then driven to zero. The NTTP request packet is then translated into one or more corresponding AHB accesses, depending on the transaction type (word aligned or nonaligned access). For example, if the request is an atomic Store, or a Load that can fit an AHB burst of specified length, then such a burst is generated. Otherwise, an AHB burst with unspecified length is generated.</p>

"Integrated circuit and method for buffering to optimize burst length in networks on chips"

'800 Patent Claim	OnePlus Product Including Snapdragon System on Chip <sup>1</sup>
	<p>signal can be generated by the IP itself and is typically linked to a certain level of urgency with which the transaction will have to be completed. For example, we can imagine associating the generation of the pressure signal when a certain threshold has been reached in the FIFO of the corresponding IP. This pressure information will be embedded in the NTTP packet at the NIU level: packets that have pressure bits equal to zero will be considered without QoS; packets with a nonzero value of the pressure bit will indicate preferred traffic class.* Such a QoS mechanism offers immediate service to the most urgent inputs and variables, and fair service whenever there are multiple contending inputs of equal urgency (BE). Within switches, arbitration decisions favor preferred packets and allocate remaining bandwidth (after preferred packets are served) fairly to contending packets. When there are contending preferred packets at the same pressure level, arbitration decisions among them are also fair.</p> <p>The Arteris NoC supports the following four different traffic classes:</p>

	<ul style="list-style-type: none"> <li>• <b>Real time and low latency (RTLL)</b>—Traffic flows that require the lowest possible latency. Sometimes it is acceptable to have brief intervals of longer latency as long as the average latency is low. Care must be taken to avoid starving other traffic flows as a side effect of pursuing low latency.</li> <li>• <b>Guaranteed throughput (GT)</b>—Traffic flows that must maintain their throughput over a relatively long time interval. The actual bandwidth needed can be highly variable even over long intervals. Dynamic pressure is employed for this traffic class.</li> <li>• <b>Guaranteed bandwidth (GBW)</b>—Traffic flows that require a guaranteed amount of bandwidth over a relatively long time interval. Over short periods, the network may lag or lead in providing this bandwidth. Bandwidth meters may be inserted onto links in the NoC to regulate these flows, using either of the two methods. If the flow is assigned high pressure, the meter asserts backpressure (flow control) to prevent the flow from exceeding a maximum bandwidth. Alternatively, the meter can modulate the flows pressure (priority) dynamically as needed to maintain an average bandwidth.</li> <li>• <b>Best effort (BE)</b>—Traffic flows that do not require guaranteed latency or throughput but have an expectation of fairness.</li> </ul>

	<p>* Note that in the NTTP packet, the pressure field allows more than one bit, resulting in multiple levels of preferred traffic.</p> <p>Networks-On-Chips Theory and Practice, <a href="https://vdoc.pub/download/networks-on-chips-theory-and-practice-embedded-multi-core-systems-6f26qivv11f0">https://vdoc.pub/download/networks-on-chips-theory-and-practice-embedded-multi-core-systems-6f26qivv11f0</a>, at 315-316.</p> <p>In addition, the Arteris Interconnect includes “a mechanism called rated adaptation, which stalls packets just enough to remove wait states from the packets, preserving a low latency.” For other traffic, the “[b]est effort traffic can be left untouched[,]” “[l]atency sensitive traffic may have its urgency modulated as a function of the transaction[,]” “[s]oft real-time traffic may have its hurry level modulated as a function of the bandwidth it receives[,]” and “[o]n the real-time modem data port, the hurry is fixed at a critical level.”</p> <p>Those effects can be mended by the insertion of buffering. In the case of peak bandwidth reduction, a simple FIFO does the job: Busy states present at the output of the FIFO do not propagate back to the input until the FIFO is full. For a peak bandwidth increase, the situation is a bit more complex. In a FIFO, wait states present at the input are only absorbed when the FIFO is not empty. Arteris proposes a mechanism called rate adaptation, which stalls packets just enough to remove wait states from the packets, preserving a low latency.</p> <p>In this second step, the architecture is modified to introduce some buffering. In our example 760 bytes of memory have been distributed across the topology. Some have been put on existing links; some required the creation of new links.</p> <p>Application driven network-on-chip architecture exploration &amp; refinement for a complex SoC, <a href="https://www.arteris.com/hs-fs/hub/48858/file-14363521-pdf/docs/springer-appdrivennocarchitecture8.5x11.pdf">https://www.arteris.com/hs-fs/hub/48858/file-14363521-pdf/docs/springer-appdrivennocarchitecture8.5x11.pdf</a>, at p. 16.</p>

	<h2>Bandwidth Limiters and Rate Regulators</h2> <p>Many times architects will want to implement QoS within their SoC but the QoS prioritization data is not available from the individual IP blocks. In this case, QoS information may be generated from within the NoC interconnect using Arteris' QoS Generator. The QoS Generator can instantiate sophisticated, and software programmable, means to regulate interconnect QoS, including:</p> <ul style="list-style-type: none"> <li>➤ Bandwidth Limiters – Bandwidth limiters cause a socket to stop accepting requests when a run-time programmable throughput threshold has been exceeded.</li> <li>➤ Rate Regulators – Rate regulators cause a socket's transactions to be demoted when a bandwidth threshold is reached. This can be considered a smoother version of the bandwidth limiter because transactions are only demoted instead of stalled.</li> </ul> <p><a href="https://www.arteris.com/end-to-end-quality-of-service-qos">https://www.arteris.com/end-to-end-quality-of-service-qos</a></p>
